Let $\mathcal{L}(\Omega, \mathcal{A}, P)$ denote the set of random variables $X : (\Omega, \mathcal{A}, P) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$.

Location-scale family

The **location-scale family** of $X \in \mathcal{L}(\Omega, \mathcal{A}, P)$ is

$$\mathcal{F}_X = \{Y \in \mathcal{L}(\Omega, \mathcal{A}, P) \mid \exists c \in \mathbb{R}, d \in \mathbb{R}^+ \text{ such that } Y \stackrel{\mathcal{D}}{=} c + dX\}.$$

It is a set of random variables closed under location and scale transformations.

- $X, Y \in \mathcal{L}(\Omega, \mathcal{A}, P)$ belong to the same location-scale family if $c \in \mathbb{R}$ and $d \in \mathbb{R}^+$ exist such that

$$F_Y(y) = F_X\left(\frac{y-c}{d}\right), \quad \forall y \in \mathbb{R}.$$

- Moreover, if X and Y are absolutely continuous:

$$f_Y(y) = \frac{1}{d} f_X\left(\frac{y-c}{d}\right), \quad \forall y \in \mathbb{R}.$$

- A random variable X is called **symmetric about** $x_0 \in \mathbb{R}$ if

$$P(X \leq x_0 - x) = P(X \geq x_0 + x), \text{ for any } x \in \mathbb{R}.$$

- If there exists no point $x \in \mathbb{R}$ such that $P(X = x) > 0$, then X is symmetric about $x_0 \in \mathbb{R}$ if and only if

$$F(x_0 - x) = 1 - F(x_0 + x), \text{ for any } x \in \mathbb{R}.$$

- If X is an absolutely continuous random variable with a density function f , then X is symmetric about $x_0 \in \mathbb{R}$ if and only if

$$f(x_0 - x) = f(x_0 + x), \text{ for any } x \in \mathbb{R}.$$

A random variable X is called **symmetric** if there exists $x_0 \in \mathbb{R}$ about which X is symmetric.

A skewness coefficient is a function

$$\begin{aligned} \gamma : \mathcal{L}(\Omega, \mathcal{A}, P) &\longrightarrow \mathbb{R} \\ X &\longmapsto \gamma(X). \end{aligned}$$

An axiomatization of the notion of symmetry (Oja, 1981)

Let $X, Y \in \mathcal{L}(\Omega, \mathcal{A}, P)$ be two random variables:

- 1 If X is symmetric, then $\gamma(X) = 0$.
- 2 $\gamma(cX + d) = \gamma(X)$ where $c, d \in \mathbb{R}$ with $c > 0$.
- 3 $\gamma(-X) = -\gamma(X)$.
- 4 If $X \preceq Y$, i.e., $F_Y^{-1}(F_X(x))$ is convex for all $x \in \mathbb{R}$, then $\gamma(X) \leq \gamma(Y)$.

Some skewness coefficients in the literature

Let $X \in \mathcal{L}(\Omega, \mathcal{A}, P)$:

- $S_P(X) = \frac{\mu - Mo(X)}{\sigma} \longrightarrow$ Pearson (1895).
- $\gamma_1(X) = \frac{E[(X - \mu)^3]}{\sigma^3} \longrightarrow$ Charlier and Edgeworth (1905).
- $\gamma'_{Me(X)}(X) = 3 \cdot \frac{\mu - Me(X)}{\sigma} \longrightarrow$ Yule (1912).
- $\gamma_p(X) = \frac{C_{1-p}(X) - 2 C_{0.5}(X) + C_p(X)}{C_{1-p}(X) - C_p(X)}$ for certain $p \in]0, 0.5[\longrightarrow$ Hinkley (1975).

Let $\mathcal{L}'(\Omega, \mathcal{A}, P)$ denote the set of absolutely continuous r.v. defined over $(\Omega, \mathcal{A}, P)$ whose cdf is strictly increasing on the preimage of $]0, 1[$ and twice differentiable.

A new family of skewness coefficients

Let $X \in \mathcal{L}'(\Omega, \mathcal{A}, P)$:

$$\gamma(X) = \frac{(\mathbf{v} - 2\mathbf{w} + \mathbf{v}^r)^T \mathbf{C}_p(X)}{(\mathbf{v} - \mathbf{v}^r)^T \mathbf{C}_p(X)} = \frac{\mathbf{a}^T \mathbf{C}_p(X)}{\mathbf{b}^T \mathbf{C}_p(X)},$$

is a family of skewness coefficients if:

- $k \in \mathbb{N}$ is odd.
- $\mathbf{C}_p(X) \in \mathbb{R}^k$ are increasingly-ordered quantiles of X such that if $C_q(X) \in \mathbf{C}_p(X)$ for some $q \in]0, 1[$, then $C_{1-q}(X) \in \mathbf{C}_p(X)$.
- $\mathbf{v}_i = 0$ for any $i \in \{1, \dots, \lceil k/2 \rceil\}$.
- $\mathbf{w}_{\lceil \frac{k}{2} \rceil} = 1$ and $\mathbf{w}_i = 0$ for any $i \neq \lceil k/2 \rceil$.

Sample version

Let $\mathbf{X} = (\mathbf{X}_1, \dots, \mathbf{X}_n)^T \in \mathbb{R}^n$ be a simple random sample from an absolutely continuous random variable X . The sample version of γ is defined as:

$$\hat{\gamma}(\mathbf{X}) = \frac{(\mathbf{v} - 2\mathbf{w} + \mathbf{v})^T \widehat{\mathbf{C}}_{\mathbf{p}}(\mathbf{X})}{(\mathbf{v} - \mathbf{v}^r)^T \widehat{\mathbf{C}}_{\mathbf{p}}(\mathbf{X})} = \frac{\mathbf{a}^T \widehat{\mathbf{C}}_{\mathbf{p}}(\mathbf{X})}{\mathbf{b}^T \widehat{\mathbf{C}}_{\mathbf{p}}(\mathbf{X})},$$

where $\widehat{\mathbf{C}}_q(\mathbf{X}) = \mathbf{X}_{(\lceil nq \rceil)}$ for any $q \in]0, 1[$.

A sufficient condition for it being well-defined:

$$n \geq \frac{1}{\min_{i=1, \dots, m} \mathbf{p}_{i+1} - \mathbf{p}_i}.$$

Asymptotic distribution (1 sample)

Let $\mathbf{X} = (\mathbf{X}_1, \dots, \mathbf{X}_n)^T$ be a random sample drawn from $X \in \mathcal{L}'(\Omega, \mathcal{A}, P)$. Then:

$$\sqrt{n} \frac{\hat{\gamma}(\mathbf{X}) - \gamma(X)}{\tau_X} \xrightarrow{\mathcal{D}} \mathcal{N}(0, 1), \quad \text{with}$$

$$\begin{aligned} \tau_X^2 = & \frac{4}{[(\mathbf{v}^T - \mathbf{v}^{rT})\mathbf{C}_p(X)]^4} \sum_{j=1}^k \sum_{i=1}^k \frac{\min\{\mathbf{p}_i, \mathbf{p}_j\}(1 - \max\{\mathbf{p}_i, \mathbf{p}_j\})}{f(\mathbf{C}_{p_i}(X))f(\mathbf{C}_{p_j}(X))} \\ & [\mathbf{v}_i(\mathbf{w}^T - \mathbf{v}^{rT}) + \mathbf{v}_i^r(\mathbf{v}^T - \mathbf{w}^T) + \mathbf{w}_i(\mathbf{v}^{rT} - \mathbf{v}^T)]\mathbf{C}_p(X) \\ & \cdot [\mathbf{v}_j(\mathbf{w}^T - \mathbf{v}^{rT}) + \mathbf{v}_j^r(\mathbf{v}^T - \mathbf{w}^T) + \mathbf{w}_j(\mathbf{v}^{rT} - \mathbf{v}^T)]\mathbf{C}_p(X). \end{aligned}$$

An analogous result holds when estimating τ_X such that $\hat{\tau}^2(\mathbf{X}) \xrightarrow{\mathcal{P}} \tau_X^2$, which can be achieved by estimating $\mathbf{C}_p(\mathbf{X})$ with $\mathbf{X}_{(\lceil np \rceil)}$, and f with its kernel density estimator f_n .

Theorem 1: Asymptotic distribution (2 samples)

Let $\mathbf{X} = (\mathbf{X}_1, \dots, \mathbf{X}_n)^T$ and $\mathbf{Y} = (\mathbf{Y}_1, \dots, \mathbf{Y}_m)^T$ be two independent random samples drawn from two independent random variables $X, Y \in \mathcal{L}'(\Omega, \mathcal{A}, P)$. Then:

$$\frac{(\hat{\gamma}(\mathbf{X}) - \gamma(X)) \pm (\hat{\gamma}(\mathbf{Y}) - \gamma(Y))}{\sqrt{\frac{\tau_X^2}{n} + \frac{\tau_Y^2}{m}}} \xrightarrow{\mathcal{D}} \mathcal{N}(0, 1),$$

where τ_X^2 and τ_Y^2 are defined as before.

Remark: We assume $n = g(m)$ with $g : \mathbb{N} \rightarrow \mathbb{N}$ an increasing function such that $\lim_{m \rightarrow \infty} \frac{m}{g(m)} = \lambda \in]0, \infty[$, i.e., both sample sizes grow to infinity at comparable rates.

Framework

In the following, we assume that

- $\mathbf{X} = (\mathbf{X}_1, \dots, \mathbf{X}_n)^T$ and $\mathbf{Y} = (\mathbf{Y}_1, \dots, \mathbf{Y}_m)^T$ are two independent random samples drawn from two independent random variables $X, Y \in \mathcal{L}'(\Omega, \mathcal{A}, P)$.
- $n = g(m)$ with $g : \mathbb{N} \rightarrow \mathbb{N}$ increasing such that $\lim_{m \rightarrow \infty} \frac{m}{g(m)} = \lambda \in]0, \infty[$.

We aim to test whether the underlying distributions of $\mathbf{X}$ and $\mathbf{Y}$ belong to the same location-scale family, which might be **known** or **unknown**.

- A new family of coefficients
- Sample version of the new family of coefficients

3 Two-sample goodness-of fit tests to a location-scale family

- Known location-scale family
- Unknown location-scale family

4 Conclusions and future work

Setting up the hypotheses of the test ($\mathcal{F}$ known)

The hypotheses in a goodness-of-fit test to a **known** location-scale family $\mathcal{F}_0$ are the following:

$$\begin{cases} H_0 : X \text{ and } Y \text{ belong to the same location-scale family } \mathcal{F}_0 . \\ H_1 : X \text{ and } Y \text{ **do not** belong to the same location-scale family } \mathcal{F}_0 . \end{cases}$$

- From [Theorem 1](#), it follows that $\frac{(\hat{\gamma}(\mathbf{X}) - \gamma(X)) + (\hat{\gamma}(\mathbf{Y}) - \gamma(Y))}{\sqrt{\frac{\tau_X^2}{n} + \frac{\tau_Y^2}{m}}} \xrightarrow{\mathcal{D}} \mathcal{N}(0, 1)$.
- Under H_0 , it holds that $\mathcal{F}_X = \mathcal{F}_Y = \mathcal{F}_0$. Therefore, by [Axiom 2](#),
 - $\gamma(X) = \gamma(Y) \implies \gamma(X) + \gamma(Y) = 2\gamma_{\mathcal{F}_0}$.
 - $\tau_X = \tau_Y = \tau_{\mathcal{F}_0}$.

Test statistic and rejection region

To perform the test, the following statistic is used

$$\frac{\sqrt{nm}}{\sqrt{n+m}} \frac{(\hat{\gamma}(\mathbf{X}) + \hat{\gamma}(\mathbf{Y}) - 2\gamma_{\mathcal{F}_0})}{\tau_{\mathcal{F}_0}} \xrightarrow[H_0]{\mathcal{D}} \mathcal{N}(0, 1).$$

$$\text{R.R.} = \left\{ (\mathbf{x}, \mathbf{y}) \in \mathbb{R}^{n+m} \mid |\hat{\gamma}(\mathbf{x}) + \hat{\gamma}(\mathbf{y}) - 2\tau_{\mathcal{F}_0}| > \tau_{\mathcal{F}_0} \sqrt{\frac{n+m}{nm}} z_{1-\alpha/2} \right\}.$$

Experimental framework

- Goodness-of fit to the **normal**, **uniform** and **(shifted) exponential** distributions.
- Significance level $\alpha = 0.05$.
- The power of the tests is estimated by Monte Carlo simulation (10^5 replications).
- Expected behaviour:
 - 1 Under H_0 : Power $\in [0; 0.0511]$.
 - 2 Under H_1 : Power ≈ 1 .
- $n = 100$.
- $m \in \{10, 50, 100, 200\}$.
- $\mathbf{w} = (0, 0, 1, 0, 0)^T$.
- $\mathbf{v} = \lambda (0, 0, 0, 1, 0)^T + (1 - \lambda) (0, 0, 0, 0, 1)^T$, with $\lambda \in \{0, 1/4, 1/2, 3/4, 1\}$
- $\mathbf{C}_p$ such that $\mathbf{p} = (1/6, 2/6, 3/6, 4/6, 5/6)^T$.

Setting up the hypotheses of the test ($\mathcal{F}$ unknown)

The hypotheses in a goodness-of-fit test to an **unknown** location-scale family are the following:

$$\begin{cases} H_0 : X \text{ and } Y \text{ belong to the same location-scale family .} \\ H_1 : X \text{ and } Y \text{ **do not** belong to the same location-scale family .} \end{cases}$$

- From [Theorem 1](#), it follows that $\frac{(\hat{\gamma}(\mathbf{X}) - \gamma(X)) - (\hat{\gamma}(\mathbf{Y}) - \gamma(Y))}{\sqrt{\frac{\tau_X^2}{n} + \frac{\tau_Y^2}{m}}} \xrightarrow{\mathcal{D}} \mathcal{N}(0, 1)$.
- We estimate $\hat{\tau}(\mathbf{X})$ and $\hat{\tau}(\mathbf{Y})$ such that $\hat{\tau}^2(\mathbf{X}) \xrightarrow{P} \tau_X^2$ and $\hat{\tau}^2(\mathbf{Y}) \xrightarrow{P} \tau_Y^2$.
- Under $H_0: \gamma(X) = \gamma(Y) \implies \gamma(X) - \gamma(Y) = 0$ because $\mathcal{F}_X = \mathcal{F}_Y$ and [Axiom 2](#).

Test statistic and rejection region

To perform the test, the following statistic is used

$$\frac{\hat{\gamma}(\mathbf{X}) - \hat{\gamma}(\mathbf{Y})}{\sqrt{\frac{m \hat{\tau}^2(\mathbf{X}) + n \hat{\tau}^2(\mathbf{Y})}{n m}}} \xrightarrow[H_0]{\mathcal{D}} \mathcal{N}(0, 1).$$

$$\text{R.R.} = \left\{ (\mathbf{x}, \mathbf{y}) \in \mathbb{R}^{n+m} \left| \left| \frac{\hat{\gamma}(\mathbf{x}) - \hat{\gamma}(\mathbf{y})}{\sqrt{m \hat{\tau}^2(\mathbf{x}) + n \hat{\tau}^2(\mathbf{y})}} \right| > \frac{Z_{1-\alpha/2}}{\sqrt{n m}} \right. \right\}.$$

4 Conclusions and future work

Conclusions of the experimental setup

- **Under H_0 :** Significance level $\alpha = 0.05$ is preserved for any sample size m and weight vector $\mathbf{v}$.
- The tests have difficulty distinguishing location-scale families whenever the skewness coefficient takes the same value.
- **Under H_1 :** The performance is more accurate when the location-scale family under H_0 and the samples involved in the tests differ in their skewness coefficient.
- **Choice of weight vector $\mathbf{v}$:**
 - Under H_0 : Irrelevant
 - Under H_1 : Right-weighted vectors $\mathbf{v}$.

To be continued...

- 1 To extend the definition of the new family of skewness coefficients to a **wider range of weight vectors**.
- 2 To introduce a statistical measure (kurtosis) that allows us to **distinguish between random variables** with the same value of skewness → Jarque-Bera test.
